Shaping,
packetization
and
computation
time

Swapping
between
function
classes

Experiment

Conclusion

- A theory designed to compute *guaranteed bounds* on delays.
- With a strong mathematical background: $(\min, +)$ algebra
 - Basic object: non-decreasing, non-negative functions

$$\mathcal{F} = \{f : \mathbb{R}_+ \rightarrow \mathbb{R}_+ \mid x < y \implies f(x) \leq f(y)\}$$

- Three basic operations: the convolution $*$, deconvolution \oslash , the sub-additive closure f^* .

$$(f * g)(t) = \inf_{0 \leq u \leq t} (f(t - u) + g(u)) \quad (1)$$

$$(f \oslash g)(t) = \sup_{0 \leq u} (f(t + u) - g(u)) \quad (2)$$

$$f^* = \delta_0 \wedge f \wedge (f * f) \wedge (f * f * f) \wedge \dots \quad (3)$$

packetization
and
computation
time

Swapping
between
function
classes

Experiment

Conclusion

Two basic objects:

■ *Flow*:

- modelling: $R \in \mathcal{F} = \{\mathbb{R}^+ \rightarrow \mathbb{R}^+, \text{non-decreasing}\}$
- semantics: $R(t)$, cumulative amount of data up to t

■ *Server*:

- modelling: $S \in \mathcal{F} \times \mathcal{F}: R \xrightarrow{S} R' \implies R' \leq R$
- semantics: relation between some input and some output, no loss, output comes after input ($R'(t) \leq R(t)$)

■ *delay*:

$$d(R, S) \leq \max_{R \xrightarrow{S} R'} h(R, R')$$

$h(R, R')$: horizontal deviation

Contract modelling

An efficient
and simple
class

M. Boyer

- Flow contract: arrival curve α

$$\begin{aligned} R \prec \alpha &\iff \forall t, \Delta \in \mathbb{R}^+ R(t + \Delta) - R(t) \leq \alpha(\Delta) \\ &\iff R \leq R * \alpha \end{aligned}$$

- Server contract: service curve

- simple service of curve β

$$R \xrightarrow{S} R' \iff R' \geq R * \beta$$

- strict service of curve β

for all backlogged period $[t, t + \Delta[$
(i.e. $\forall x \in [t, t + \Delta[: R'(x) < R(x)$):
 $R'(t + \Delta) - R'(t) \geq \beta(\Delta)$

- Results: $R \xrightarrow{S} R'$, $R \prec \alpha$, S has service curve β :

$$\begin{aligned} R' &\prec \alpha \circ \beta \\ d(R, S) &\leq h(\alpha, \beta) \end{aligned}$$

2 Shaping, packetization and computation time

3 Swaping between function classes

4 Experiment

5 Conclusion

Shaping on links

A link is shared by a set of flows: what is the throughput of this set ?

- Principle: whatever the applicative throughput is, is it limited by the links capacity
Also known has:
 - Serialisation: the frames of the different flows can not be sent at the same time
 - Grouping: computes per-group throughput, not per-flow
- Interest: considering long term rate ρ and instantaneous burst b
 - applicative flows: small ρ , big b
 - link: big ρ , null b
- Impact: up to 40% in industrial system

Shaping and network calculus

An efficient and simple class

M. Boyer

Network calculus

Shaping, packetization and computation time

Swapping between function classes

Experiment

Conclusion

Let S be a server, with *shaping curve* σ , then, the output is constrained by σ .

If the output is constrained by α' , it is by $\alpha' \wedge \sigma$.

$$R \xrightarrow{S} R' \implies R' \prec \sigma$$
$$R \prec \alpha, S \succeq \beta \implies R' \prec \sigma \wedge (\alpha \otimes \beta)$$

Modelling a packetized flow

An efficient
and simple
class

M. Boyer

Network
calculus

Shaping,
packetization
and
computation
time

Swapping
between
function
classes

Experiment

Conclusion

Common example: sporadic flow

- inter emission “period”: T
- frame size (fixed or max): b

Two modelling:

- fluid (“token bucket”): affine function, continuous
- packetized: stair-case functions, discontinuous

Fluid modelling: the virtual burst problem

An efficient
and simple
class

M. Boyer

Network
calculus

Shaping,
packetization
and
computation
time

Swapping
between
function
classes

Experiment

Conclusion

Jitter “shifts” the arrival curve:

- if jitter $<$ period: instantaneous burst unchanged
- in fluid modelling: creation of virtual burst \implies increase bounds

Putting all together

An efficient and simple class

M. Boyer

Network calculus

Shaping, packetization and computation time

Swapping between function classes

Experiment

Conclusion

- fluid + shaping: concave piecewise linear function (CPL)
Efficient min, max, sum
Implementation in floating points
- stair-case modelling: general class (UPP)
Complex min, max, sum
Implementation in exact rationals (\mathbb{Q})

Outline

Getting the better of each class

An efficient
and simple
class

M. Boyer

Network
calculus

Shaping,
packetization
and
computation
time

Swapping
between
function
classes

Experiment

Conclusion

Classes strengths/weaknesses:

- jitter effect: stair-case class
- summing (“grouping”): CPL class
- shaping: CPL class

Idea:

- keeping stair-case for individual flow constraint
- converting into CPL when summing and shaping

From stair-case to CPL

An efficient
and simple
class

M. Boyer

Network
calculus

Shaping,
packetization
and
computation
time

Swapping
between
function
classes

Experiment

Conclusion

Figure: CPL overapproximation of a stair-case function

$$cpl(b\nu_{T,\tau}) = \gamma_{\frac{b}{T-\tau}, nb} \wedge \gamma_{\frac{b}{T}, b(1+\tau/T)} \quad (4)$$

Algorithm adaptation

An efficient
and simple
class

M. Boyer

Network

Shaping,
packetization
and
computation
time

Swaping
between
function
classes

Experiment

Conclusion

```
1 Function GroupAC( $S_j, \mathcal{F}$ ) ;
2 Assert( $\mathcal{F} \subset S_j^\bullet$ ) ;
3 begin
4   if  $S_j = S_0$  then
5     return  $\sum_{F_i^k \in \mathcal{F}} \alpha_i^k$  ; //  $\mathcal{F} \subset S_j^\bullet \implies k = 0$ 
6   else if  $S_j$  is an aggregate server then
7     if  $d_j = \text{null}$  then
8        $\alpha^{S_j} \leftarrow \sum_{S_p \in \bullet\bullet S_j} \text{GroupAC}(S_p, S_p^\bullet \cap \bullet S_j)$  ;
9        $d_j = h(\alpha^{S_j}, \beta_j)$  ;
10      foreach  $F_i^k \in \bullet S_j$  do
11        return  $\alpha_i^{k+1} \leftarrow (\alpha_i^k \oslash \delta_{d_j})^*$  ;
12      return  $(\sigma_j \wedge \sum_{F_i^k \in \mathcal{F}} \alpha_i^k)^*$ 
```

Adaptation: replace $\sum_{F_i^k \in \mathcal{F}} \alpha_i^k$ by $\sum_{F_i^k \in \mathcal{F}} \text{cpl}(\alpha_i^k)$

Experiment

Conclusion

Pessimism evaluation

An efficient
and simple
class

M. Boyer

- Method comparison: based on upper bound (UB_m)
- Best comparison: based on pessimism

$$\text{pess}_m = UB_m - WCTT$$

- Worst case unknown ($WCTT$)
- Delay lower bound: trajectorial based approach (LB)

$$LB \leq WCTT \leq UB_m$$

$$\text{pess}_m \leq UB_m - LB$$

classes

Experiment

Conclusion

- Two critical aspects: shaping and packetization
- Two existing methods:
 - fluid: bad packetization, quick computation
 - stair-case: good packetization, longer computation
- Contribution: trade-off tightness/computation time
- Don't use CPL, use $CPL/b.\nu_{T,\tau}$
 - simple to implement
 - low computation time over-head
 - significant bound improvement
- Perspective: use in optimisation loop
 - quick computation in first iterations
 - longer computation to finalise
